Abstract: During the autumn season a field experiment was conducted at Assam Agricultural University, ICR Farm, Jorhat, Assam to compare three different direct seeded upland rice varieties under different integrated weed and nutrient management practices. The experiment was carried out in factorial randomized block design replicated thrice with 15 treatments involving 3 varieties; Inglongkiri, Maizubiron and Rasi adopting 5 treatments of weed and nutrient management, *i.e.* 20-10-10 kg/ha N-P₂O₅-K₂O + pretilachlor @ 750 g/ha followed by grubber 30 DAS (W₁), 30-15-15 kg/ha N-P₂O₅-K₂O + pretilachlor @ 750 g/ha followed by grubber 30 DAS + Vermicompost @ 1 t/ha (at sowing & 30 DAS) + Sesbania (Sesbania aculeata) green mulch (up to 30 days) (W₃), 10-5-5 kg/ha N-P₂O₅-K₂O + pretilachlor @ 750 g/ha followed by grubber 30 DAS with intra-row spacing 15cm (W₄), and 20-10-10 kg/ha N-P₂O₅-K₂O + Weedy check (W₅). The physico-chemical properties of soil at harvest were not significantly influenced by variety as well as weed and nutrient management practices. Application of 10-5-5 kg/ha N-P₂O₅-K₂O, vermicompost @ 1t/ha, Sesbania green mulch, pretilachlor @ 750g a.i. /ha and grubber 30 DAS showed significantly higher soil microbial biomass carbon (323.72) at 30 DAS, significantly higher bacterial count at 75 DAS (23.07) and higher fungal count at 60 DAS (10.67), significantly higher NO₃-N at 35, 55 and 70 DAS, and NH₄-N at 15 DAS and 70 DAS. An increase in yields was revealed as evident by higher grain and straw yield for all the three varieties observed with pre-emergence application of pretilachlor (750 g a.i./ha) + grubber 30 days after sowing + 30-15-15 kg/ha N-P₂O₅-K₂O.

Introduction

Rice (*Oryza sativa* L.) is one of the most important food crops in the world, and staple food for more than 50% of the global population. With increasing population and increasing incomes, the demand for rice will continue to grow in coming decades. Presently, rice is cultivated in 43.79 Mha area with 112.91 Mt. production while wheat is cultivated in 29.58 Mha area with a production of 99.70 Mt. [1]. Introduction of high-yielding varieties along with improved crop management practices, access to irrigation water and chemical inputs during the green revolution period has led to impressive increase in system productivity.

Transplanting after repeated puddling is the conventional method of rice (Oryza sativa) growing which is not only intensive water user but also cumbersome and laborious. Different problems like lowering water table, scarcity of labour during peak periods, deteriorating soil health demands some alternative establishment method to sustain productivity of rice as well as natural resources. Increasing water scarcity, water loving nature of rice and increasing labour wages trigger to switch for such alternative crop establishment methods which can increase water productivity. The process of change has begun to transform the paradigm of agricultural research and development. Direct seeded rice crop has a higher nutrient requirement as compared to a transplanted crop because of the higher plant density and greater production of biomass in the vegetative phase [2]. Proper weed management practices along with integrated nutrient management [3], more particularly with major nutrients, significantly influence the crop productivity in upland situations. Fertilizer management can definitely alter the competitive balance between crops and weeds, but methods to incorporate it into integrated weed management are yet to be developed [4].

Integrated use of chemical fertilizers with manures, compost and green manure crops is very important for sustainable rice production especially under rainfed upland conditions [5].

Chemical fertilizers sustain short-term productivity of agro-ecosystems, while their indiscriminate use reduces soil fertility [6]. Soil microbial activities are enhanced by application of manure compost that improve the crop growth, and restrain the pests and diseases. In increasing nutrient availability to crops manure compost has been found to be better than chemical fertilizers thereby improving grain yield in a cost-effective and environmental friendly manner [7,8]. Addition of the same can also increase levels of organic matter and improve soil porosity, structural stability, moisture, and nutrient availability, as well as biological activity [9].

Materials and methods

A field experiment was conducted at ICR farm of Assam Agricultural University, Jorhat, Assam during the autumn season. The soil of experimental plot was sandy loam in texture with pH 4.95, organic carbon of 0.53% and 263.87, 22.10 and 134.71 kg/ha N, P and K, respectively. The experiment was carried out in factorial randomized block design replicated thrice with 15 treatments and 3 varieties; Inglongkiri, Maizubiron and Rasi adopting 5 treatments of weed and nutrient management, i.e. 20-10-10 kg/ha N-P₂O₅- K₂O + pretilachlor @ 750 g/ha followed by grubber 30 DAS (W₁), 30-15-15 kg/ha N-P₂O₅-K₂O + pretilachlor @ 750 g/ha followed by grubber 30 DAS (W₂), 10-5-5 kg/ha N-P₂O₅-K₂O + pretilachlor @ 750 g/ha followed by grubber 30 DAS + Vermicompost @ 1 t/ha (at sowing & 30 DAS) + Sesbania (Sesbania aculeata) green mulch (up to 30 days) (W₃), 10-5-5 kg/ha

N-P₂O₅-K₂O + pretilachlor @ 750 g/ha followed by grubber 30 DAS with intra-row spacing 15cm (W₄), and 20-10-10 kg/ha N-P₂O₅-K₂O + Weedy check (W₅). The nutrients N, P₂O₅, K₂O were applied in the form of urea, single super phosphate (SSP) and muriate of potash (MOP), respectively. The required amounts of P₂O₅ fertilizers, as per treatment, were applied as basal in the lines

one day prior to sowing and thoroughly mixed with the soil. The required amounts of N and K_2O fertilizers, as per treatment, were applied in two splits. Half of nitrogenous and potassic fertilizers was applied 20 days after sowing. The second top dressing with the remaining quantities of nitrogenous and potassic fertilizers was done in 40 days after sowing.

The vermicompost @ 1 t/ha was applied in rows in two equal splits *i.e.* at basal and 30 DAS. Sesbania aculeata as green mulch was grown and incorporated in soil at 30 days DAS. The pre-emergence application of pretilachlor (Craze 50 EC) was made by spraying the herbicide spray solution on the soil surface uniformly, one day after sowing of rice seed. The spray solution, on the basis of spray volume of 500 l/ha, was sprayed as per the treatments by using knapsack sprayer. While applying the pre-emergence herbicide, care was taken to ensure that the herbicide drift dose not reaches to adjacent experimental plots. Mechanical weeding, as per treatment, was done on 30 DAS by using manually operated grubber [10-12].

Results and discussion

Physico-chemical properties of soil

The soil physico-chemical properties like, pH, organic carbon, available N, P_2O_5 and K_2O did not differ significantly amongst the varieties as well as weed and nutrient management practices.

This might be due to the fact that these physico-chemical properties of soil, generally, do not change significantly over short period of time [13].

Soil moisture content (%)

The data on soil moisture content at 30, 60, 90 DAS and at harvest of crop are presented in [Table-2]. Soil moisture content varied from 19.09 % to 20.88 % throughout the crop growth period.

NO₃--N and NH₄+-N content in soil

Most plants absorb both NO_3 - and NH_4 + mineral forms of N [14]. NO_3 -N predominates in the upland rice cultivation [15]. No significant influence was observed on NO_3 --N and NH_4 +-N due to varieties. Application of 10-5-5 kg/ha N- P_2O_5 - K_2O along with vermicompost @ 1t/ha, sesbania green mulch, pretilachlor @ 750g a.i./ha and grubber at 30 DAS showed significantly higher NO_3 --N at 15 and 35 DAS, and NH_4 +-N at 15 DAS, 55 DAS and 70 DAS. This might be due to application of fertilizers at sowing, 15 DAS and 40 DAS along with incorporation of

vermicompost at sowing and 30 DAS. Moreover, this treatment also recorded significantly higher microbial population as well as soil microbial biomass carbon. Less amount of NH_4+-N in upland condition might be due to its oxidation to NO_3 and higher NO_3--N is attributed to nitrification of NH_4+-N under upland condition [16].

Soil microbial biomass carbon

There was no significant difference in soil microbial biomass carbon at all three periods *i.e.* at initial, 30 DAS and at harvest of crop growth due to varieties. At 30 DAS, weed and nutrient management practice of application of 10-5-5 kg/ha N- P_2O_5 - K_2O , vermicompost @ 1t/ha, sesbania green mulch, pretilachlor @ 750g a.i./ha and use of grubber 30 DAS showed significantly higher soil microbial biomass carbon (323.72) followed by that (308.53) in application of 30-15-15 kg/ha N- P_2O_5 - K_2O along with pretilachlor @ 750 g a.i./ha and grubber 30 DAS. This might be due to application of organic source of nutrients including growing sesbania up to 30 DAS and then incorporated into soil which may improve the microbial activities. A similar finding was also reported by Shen *et al.*, (1984) [17]. Table-8.1 Interaction effect of variety with weed and nutrient management practices on grain yield (kg/ha) of rice

Bacterial and fungal populations

Varieties could not bring about significant difference in bacterial and fungal population at all the three stages *i.e.* initial, 30 DAS and at harvest of crop. Application of 10-5-5 kg/ha $N-P_2O_5-K_2O$ along with vermicompost @ 1t/ha, sesbania green

mulch, pretilachlor @ 750 g a.i./ha and working with grubber 30 DAS showed significantly higher bacterial population at 75 DAS and fungal population at 40 DAS. This might be due to application of organic manure *i.e.* (i) vermicompost at initial and 30 DAS (ii) growing of sesbania as green mulch which was incorporated into soil at 30 DAS. Similar findings were reported by Zia *et al.* (2001) and D'Andrea *et al.* (2004).

Grain yield and straw yield (kg/ha)

A perusal of the findings revealed that there was no significant difference in grain yield amongst the three varieties tested while Inglonkiri showed significantly higher straw yield. It might be due to significantly higher plant height at harvest in Inglongkiri. Regarding the factor, weed and nutrient management, application of 30-15-15 kg/ha N-P₂O₅-K₂O along with pretilachlor @ 750 g a.i./ha and use of grubber 30 DAS (W2) showed significantly higher grain yield and straw yield. The higher grain yield might be due to better nutrition of rice crop owing to application of higher dose of major nutrients as well as reduction in crop weed competition due to combined methods of weed control i.e. chemical and mechanical, that resulted in statistically superior growth characters (LAI, number of tillers and dry matter accumulation) and yield attributing characters (number of panicles, panicle length and number of filled grains). Kavitha et al., (2010) [18] reported that application of pretilachlor suppressed the weed in the early growth stages of autumn rice leading to higher yield. The higher straw yield might be due to higher amount of dry matter production at 30 and 60 DAS in W2. The improved cultivars produced higher yields than traditional cultivars in both high and low fertility conditions [19]. The grain and straw yield were affected significantly by the interaction effect of varieties and weed and nutrient management practices. The results revealed that higher grain yield was given by Rasi, when combined with application of 30-15-15 kg/ha N-P₂O₅-K₂O along with pretilachlor @ 750 g a.i./ha and use of grubber 30 DAS (W2) while Inglongkiri showed significantly higher straw yield when combined with W2.

Conclusion

The pH, organic carbon, available N, P2O5 and K2O in soil at harvest were not significantly influenced by variety or weed and nutrient management practices. Varieties showed no significant effect on soil microbial biomass carbon, bacterial and fungal count, and NO₃-N and NH₄-N content in soil. However, application of 10-5-5 kg/haN-P₂O₅-K₂O, vermicompost @ 1t/ha, Sesbania green mulch, pretilachlor @ 750g a.i./ha and grubber 30 DAS showed significantly higher soil microbial biomass carbon (323.72) at 30 DAS and also gave significantly higher bacterial count at 75 DAS (23.07) and higher fungal count at 60 DAS (10.67). This was followed by that in 30-15-15 kg/haN-P₂O₅-K₂O along with pretilachlor @ 750 g a.i./ha and grubber 30 DAS. Application of 10-5-5 kg/ha N-P₂O₅-K₂O along with vermicompost @ 1 t/ha, Sesbania green mulch, pretilachlor @ 750 g a.i. /ha and grubber 30 DAS gave significantly higher NO₃-N at 35, 55 and 70 DAS, and NH₄-N at 15 DAS and 70 DAS. Variety Inglongkiri resulted significantly higher straw yield (21.05) but was at par with that in Maizubiron (21.03) but both were significantly superior to that in Rasi (20.17). The grain yield (2087) and straw yield (2631) recorded with application of 30-15-15 kg/ha N-P2O5-K2O along with pretilachlor @ 750 g a.i. /ha and grubber 30 DAS was significantly higher than that (1877 and 2533) in application of 20-10-10 kg/haN-P₂O₅-K₂O along with pretilachlor @ 750 g/ha and working with grubber 30 DAS.

Application of research: Study of different direct seeded upland rice varieties under different integrated weed and nutrient management practices

Research Category: Soil Science

Acknowledgement / Funding: Authors are thankful to Assam Agricultural University, Jorhat, 785013, Assam, India

**Minor Research Guide or Chairperson of research: Dr Nilay Borah

University: Assam Agricultural University, Jorhat, 785013, Assam, India Research project name or number: MSc Thesis

Author Contributions: All authors equally contributed

Author statement: All authors read, reviewed, agreed and approved the final manuscript. Note-All authors agreed that- Written informed consent was obtained from all participants prior to publish / enrolment

Study area / Sample Collection: ICR Farm, Jorhat, Assam

Cultivar / Variety / Breed name: Oryza sativa - Inglongkiri, Maizubiron, Rasi

Conflict of Interest: None declared

Ethical approval: This article does not contain any studies with human participants or animals performed by any of the authors. Ethical Committee Approval Number: Nil
